

# Osmoregulation & Excretion

Paige Lehman, Mattie Barberis, Ian Russell

# What is Osmoregulation?

Osmoregulation is the process by which animals control solute concentrations and water.

- Form of Homeostasis

Types!

- Pee
- Sweat
- Tears

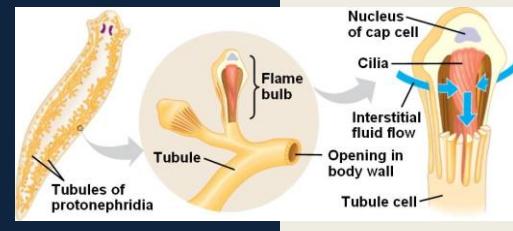

# Evolutionary Importance

Osmoregulator- They control their  
Osmoregulatory

Osmoconformer- They are isoosmotic with their  
surroundings

Animals that lay eggs can turn their waste into  
solute to not hurt them

# Excretory System

Protonephridia- a network of dead end tubules connected to external openings.

- occur in flatworms

Cilia attract water and solutes from the blood.

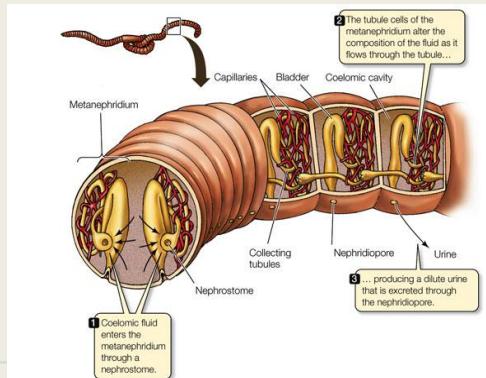

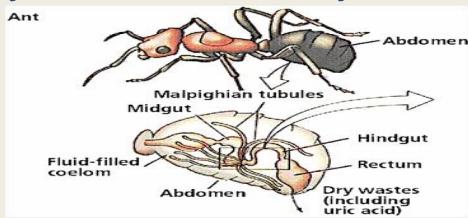

- then it's excreted.
  - low solute concentration.

Metanephridia- in excretory organs that open internally, cilia draw fluid into a collecting tubule, tubule opens to the outside (bladder).

- Found in earthworms

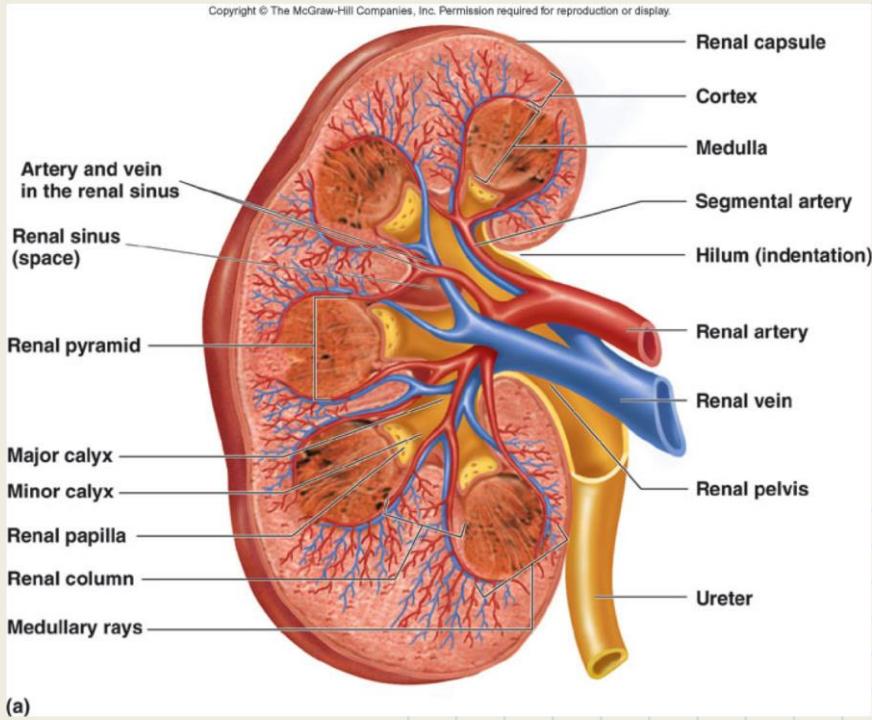

Malpighian tubules- way that arthropods excrete

Kidneys- tubules carry urine out of the kidney to the bladder

# Excretory System

Kidneys- Filters the blood, the waste is excreted

# Kidneys Video

<http://youtu.be/apUeuBA8Rqk>

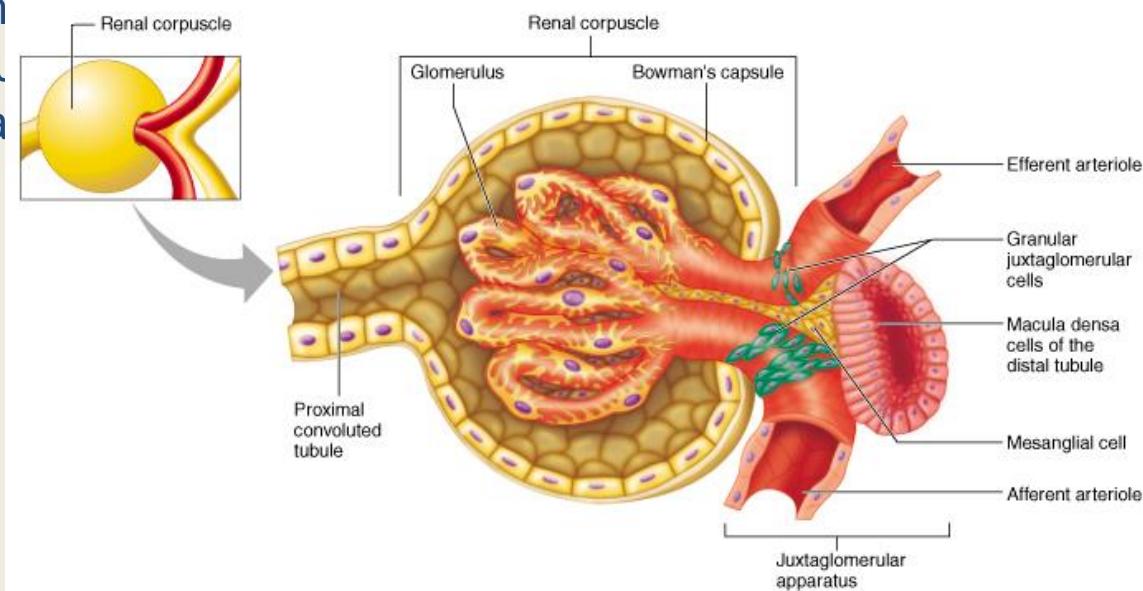

# Bladder System

- The renal artery pumps blood through the kidneys
  - The renal vein then drains the blood
- The Ureter is where the blood exits the kidney
  - Drains into the urinary bladder
- Exits through the urethra

# Renin-Angiotensin-Aldosterone

-The RAAS involves a specialized tissue called the Juxtaglomerular apparatus (JGA), located near the afferent arteriole that supplies blood to the glomerulus.

-RAAS is a hormone system that regulates blood pressure and water balance

# Diseases and Disorders

Kidney Cancer- cancer affecting your kidneys

Diabetes- can't produce your own insulin

Urinary Tract Infections- An infection in you're urinary tract

Antiphospholipid syndrome- your immune system attacks normal proteins in the blood, forms blood clots in the kidneys

# Different types of Wastes

Ammonia- needs a lot of water, happens in aquatic creatures, toxic, excreted in large volumes

Urea- low toxicity, stored safely at high concentrations, little water loss, downside= costs a lot of energy to convert ammonia to urea

Uric Acid- in insects, reptiles, birds. non toxic, doesn't readily dissolve in water, semi solid paste excretion, very little water loss, requires more energy than urea

# Energetics of Osmoregulation

- Osmoregulators expend energy to maintain osmotic gradients.
  - do this by active transport.
- If an animal has a very different osmoregularity than its surroundings, then it has to expend more energy.
- Osmolarity- the total solute concentration expressed as moles of solute per liter.

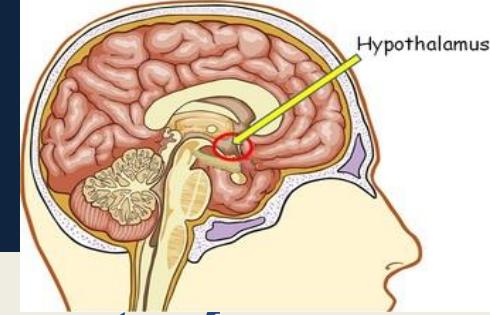

# Transport Mechanisms

-Transport Epithelium- one or more layers of specialized epithelial cells that regulate solute movements, move specific solutes in controlled amounts in specific directions, usually arranged in complex tubular networks with extensive surface area.

## Interdependence of the system with other body systems

- The kidneys rely on blood flow to remove waste
  - The endocrine system is the major controller of the excretory system
- The circulatory system with blood helps move blood
  - The urinary system relies on the digestive system to bring waste to excrete

# Regulation Mechanisms

- The Hypothalamus monitors the amount of water in the body
- The Antidiuretic Hormone causes more water to be retained by the kidneys when water levels are low
- Aldosterone causes the retention of water in the body by increasing levels of sodium and potassium in the blood.

# Urinalysis and Tests

- Its the analyzing of urine. It involves the examining the appearance, concentration, and content of urine
- 3 ways to analyze
  - Visual- simply looking at the urine
  - Dipstick test- Place a stick with chemical in the urine
  - Microscopic test- place it under a microscope

# Osmoregulation and hormone control

-Antidiuretic Hormone- also called vasopressin and is produced in the Hypothalamus of the brain and stored in the posterior pituitary gland.

- Osmoreceptor cells in the Hypothalamus monitor the osmolarity of blood and regulate the release of ADH to the posterior pituitary.

- An increase in the osmolarity above 300 mOsm/L cause more ADH to be released into the blood stream

- Eventually make the epithelium more permeable to water.

# Thermoregulation

- Helps maintain core internal body temperature
- Endotherms- regulate own internal body temperature
- Ectotherms- Rely on the external environment to help with regulation of their own body
